These are example patterns, not prescriptions. Babies vary, and the right schedule is the one where nappies, weight and your own sanity all hold up. Breastfeeds are always on demand; the "schedule" is really about which feeds are formula.

Amounts for the formula feeds below come from the CDC and the American Academy of Pediatrics and are averages, not targets [\[4\]](#) [\[6\]](#). Let your baby stop when full [\[4\]](#).

Newborn (0–6 weeks): protect supply first

Most newborns feed 8–12 times in 24 hours, breast or bottle [\[4\]](#) [\[7\]](#). This is the period when supply is being set, which is why every major body advises establishing breastfeeding before adding formula [\[7\]](#) [\[8\]](#) [\[9\]](#).

If you must supplement now — on medical advice for weight, jaundice or low supply — the pattern that protects breastfeeding best is **breastfeed first, then offer a small top-up**, and express after any feed where the baby did not drain the breast [\[3\]](#) [\[7\]](#). Typical formula amounts at this age are 1–2 oz (30–60 ml) per feed in the first days, rising to 3–4 oz (90–120 ml) by about a month [\[4\]](#) [\[6\]](#).

Time	Feed
Every 2–3 h round the clock	Breastfeed; top-up only if advised
After any short breastfeed	Express 10–15 min
